Git & GitHub Basics
Short Report

Parikshit Task 1

1.Introduction
Git is a distributed version control system used to track changes in files and code. GitHub is an online platform that hosts Git repositories and supports collaboration. Git and GitHub are often used together for software development & project management.

2.Git & GitHub
Git is the version-control software running on a computer locally. It captures changes, lets developers make branches and allows them to go back to previous versions. GitHub is a web-based service that allows Git repositories to be stored remotely, and allows multiple people to collaborate and share.

3.What I learned-
Git is for version control and GitHub is for hosting Git repositories and for collaborating on them. Also learned about the basic workflow of staging, committing and pushing changes. A repository is easier to understand and maintain if it is organized and uses meaningful commit messages.

4.Basic Git Workflow

A typical workflow is:
• Create or edit files.
• Use git status to inspect changes.
• Use git add to stage changes.
• Use git commit to save a version locally.
• Use git push to upload commits to GitHub.
• Use git pull to retrieve and integrate changes from GitHub.

5. Important Commands
git init: Creates a new Git repository.

git status: Shows the current state of the working directory and staging area.

git add: Stages the current changes.

git commit -m "message":Creates a commit containing the staged changes.

git push: Uploads local commits to the remote GitHub repository.

git pull: Downloads and integrates changes from the remote repository.

git clone <repository-url>:Creates a local copy of an existing repository.
